1 General description

The TFA9894D is a high efficiency 10 V boosted class-D audio amplifier with a sophisticated SpeakerBoost and protection algorithm. It can deliver up to 5.6 W (AVG) output power into an 8 Ω speaker and up to 6.2 W (AVG) output power into 4 Ω speaker, at a battery supply voltage of 4.0 V. The internal adaptive DC-to-DC converter raises the power supply voltage up to 10 V, providing ample headroom for major improvements in sound quality.

A safe working environment is provided for the speaker under all operating conditions. The TFA9894D maximizes acoustic output while ensuring membrane displacement and voice coil temperature do not exceed their rated limits. This function is based on a speaker box model that operates in all speaker environments (e.g. free air, closed box or vented box). Furthermore, advanced signal processing ensures that the quality of the audio signal is never degraded by unwanted clipping or distortion in the amplifier or speaker.

The adaptive sound maximizer algorithm uses feedback to calculate both the temperature and the excursion accurately, allowing the TFA9894D to adapt to changes in the acoustic environment.

Internal adaptive DC-to-DC conversion boosts the supply rail to provide additional headroom and power output. The supply voltage is only raised when necessary. This maximizes the output power of the class-D audio amplifier while limiting quiescent power consumption.

The device can be configured to drive either a hands-free speaker for audio playback, or a receiver speaker, for handset playback, allowing it to be embedded in platforms supporting both a hands-free speaker and a handset speaker. The maximum output power, the gain, and the noise levels are lower in handset call use case than in hands-free call use case.

The TFA9894D also incorporates battery protection. By limiting the supply current when the battery voltage is low, it prevents the audio system from drawing excessive load currents from the battery, which could cause a system undervoltage. This circuitry minimizes the impact of a falling battery voltage by preventing unexpected device switch off due to excessive current drawn from the battery.

The device features a second order closed loop architecture, used in a class-D audio amplifier, providing excellent audio performance and high supply voltage ripple rejection. The audio input interface is TDM and the control settings are communicated via an I2C-bus interface.

The TFA9894D is available in a 48-bump wafer level chip-size package (WLCSP) with a 400 μm pitch.

2 Features and benefits

- Sophisticated SpeakerBoost and protection algorithm that maximizes speaker performance while protecting the speaker:
 - Fully embedded software, no additional license fee, or porting required
 - Fully integrated solution, including DSP, amplifier, DC-to-DC, thermal sensing
- Adaptive excursion control - guarantees that the speaker membrane excursion never exceeds its rated limit
- Real-time temperature protection - direct measurement ensures that voice coil temperature never exceeds its rated limit
- Environmentally aware - automatically adapts speaker parameters to acoustic and thermal changes including compensation for speaker-box leakage
- Clip avoidance - DSP algorithm prevents clipping even with sagging supply voltage
- Automatic bandwidth extension to increase low-frequency response
- TFA9894D high output power: 5.6 W (AVG) into 8 Ω at 4.0 V supply voltage (THD = 1 %, VBST = 10 V), 6.2 W (AVG) into 4 Ω at 4.0 V supply voltage (THD = 1 %, VBST = 9 V)
- Support handset and hands-free (4 Ω to 32 Ω) speaker configurations.
- High efficiency, low power dissipation, and low noise speaker driver (dynamic range > 110 dB).
- Adaptive DC-to-DC converter increases the supply voltage smoothly when switching between fixed boost and adaptive boost mode, preventing large battery supply spikes and limiting quiescent power consumption.
- Wide supply voltage range (fully operational from 2.7 V to 5.5 V)
- Very low noise output (typical 14 μ V with null DATA input at $F_s = 48$ kHz)
- I²C-bus control interface (400 kHz)
- Speaker current and voltage monitoring (via the TDM-bus), as well as DSP data output (with and without pilot tone) for acoustic echo cancellation (AEC) at the host.
- Various sample frequencies supported: 16 kHz, 32 kHz, 44.1 kHz, 48 kHz, and 96 kHz
- Configurable full duplex 4-wires TDM input interface.
- Programmable interrupt control via a dedicated interrupt pin
- Thermal foldback and over temperature protection
- 15 kV system-level ESD protection without external components on amplifier output

3 Applications

- Mobile phones and tablets
- Portable gaming devices
- Portable navigation devices (PND)

4 Quick reference data

Table 4-1: Quick reference data

All parameters are guaranteed for $V_{BAT} = 4.0\text{ V}$; $V_{DDD} = 1.8\text{ V}$; $V_{DDE} = 3.3\text{ V}$; $V_{DDP} = V_{BST} = 10\text{ V}$, adaptive boost mode; $L_{BST} = 1\text{ }\mu\text{H}^{[1]}$; $R_L = 8\text{ }\Omega^{[1]}$; $L_L = 44\text{ }\mu\text{H}^{[1]}$; $f_i = 1\text{ kHz}$; $f_s = 48\text{ kHz}$; $T_{amb} = 25\text{ }^\circ\text{C}$; default settings, unless otherwise specified.

8 Functional description

The TFA9894D is a highly efficient bridge tied load (BTL) class-D audio amplifier with a sophisticated SpeakerBoost and protection algorithm, depicted in block diagram of [Figure 6-1](#).

TFA9894D contains a TDM input/output interface for communicating with the audio host. The interface is compliant with standard TDM interfaces and supports a wide range of TDM configurations. It can also be configured to output current sense and voltage sense information. The audio host can use this information.

The SpeakerBoost and protection algorithm, running on a CoolFlux digital signal processor (DSP) core, maximizes the acoustical output of the speaker while limiting membrane excursion and voice coil temperature to safe levels. The mechanical protection implemented guarantees that speaker membrane excursion never exceeds its rated limit, to an accuracy of 10 %. Thermal protection guarantees that the voice coil temperature never exceeds its rated limit, to an accuracy of approximately ± 10 °C during music playback. Furthermore, advanced signal processing ensures that the audio quality always remains acceptable.

The protection algorithm implements an adaptive speaker model that is used to predict the extent of membrane excursion. The model is continuously updated to ensure that the protection scheme remains effective even when speaker parameter values change or the acoustic enclosure is modified.

The SpeakerBoost and protection algorithm boosts the output sound pressure level within given mechanical, thermal, and quality limits. An optional bandwidth extension mode extends the low frequency response up to a predefined limit before maximizing the output level. This mode is suitable for listening to high quality in quiet environments.

The frequency response of the TFA9894D can be modified via ten fully programmable cascaded second-order biquad filters. The first two biquads are processed with 48-bit double precision; biquads 3 to 10 are processed with 24-bit single precision.

At low battery voltage levels, the gain (from TDM interface to speaker output) is automatically reduced to limit battery current (when battery safeguard is enabled).

The SpeakerBoost and protection algorithm or the host application (external) can control the output volume. In the latter case, the boost features of the SpeakerBoost and protection algorithm must be disabled to avoid neutralizing external volume control.

The digital audio stream is converted into two pulse width modulated (PWM) signals which are then injected into the class-D audio amplifier. The 3-level PWM scheme supports filterless speaker drive.

When the audio stream crosses a programmable voltage threshold, an adaptive DC-to-DC converter boosts the battery supply voltage. When boosting, the DC-to-DC provides a boosted supply in line with the audio signal. In this mode, two configurations are available (two-levels mode or tracking mode (default))

9 I²C-bus interface and register settings

The TFA9894D supports the 400 kHz I²C-bus microcontroller interface mode standard. The I²C-bus is used to control the TFA9894D and to transmit and receive data. The TFA9894D can only operate in I²C slave mode, as a slave receiver or as a slave transmitter.

9.1 TFA9894D addressing

The TFA9894D is accessed via an 8-bit code. Bits 1 to 7 contain the device address. Bit 0 (R/W) indicates whether a read (1) or a write (0) operation has been requested. Four separate addresses are supported for stereo applications. Address selection is via pins ADS1 and ADS2. The levels on pins ADS1 and ADS2 determine the values of bits 1 and 2, respectively, of the device address. The generic address is independent of pins ADS1 and ADS2.

Table 9-1: Address selection via pins ADS1 and ADS2

ADS2 pin voltage (V)	ADS1 pin voltage (V)	Address	Function
0	0	01101000	for write mode
		01101001	for read mode
0	V _{DDE}	01101010	for write mode
		01101011	for read mode
V _{DDE}	0	01101100	for write mode
		01101101	for read mode
V _{DDE}	V _{DDE}	01101110	for write mode
		01101111	for read mode
don't care	don't care	00011100 (generic address)	for write mode
		00011101 (generic address)	for read mode

9.2 I²C-bus write cycle

The sequence of events that must be followed when writing data to the I²C-bus registers of the TFA9894D is detailed in [Table 9-2](#). One byte is transmitted at a time. Each register stores two bytes of data. Data is always written in byte pairs. Data transfer is always MSB first.

The write cycle sequence using SDA is as follows:

1. The microcontroller asserts a start condition (S).
2. The microcontroller transmits the 7-bit device address of the TFA9894D, followed by the R/W bit set to 0.
3. The TFA9894D asserts an acknowledge (A).
4. The microcontroller transmits the 8-bit TFA9894D register address to which the first data byte is written.
5. The TFA9894D asserts an acknowledge.
6. The microcontroller transmits the first byte (the most significant byte).

7. The TFA9894D asserts an acknowledge.
8. The microcontroller transmits the second byte (the least significant byte).
9. The TFA9894D asserts an acknowledge.
10. The microcontroller can either assert the stop condition (P) or continue transmitting data by sending another pair of data bytes, repeating the sequence from step 6. In the latter case, the targeted register address has been auto-incremented by the TFA9894D.

Table 9-2: I²C bus write cycle

Start	TFA9894D address	R/W		TFA9894D first register address		MSB		LSB		More data...	Stop
S	01101A ₂ A ₁	0	A	ADDR	A	MS1	A	LS1	A	<..>	P

9.3 I²C-bus read cycle

The sequence of events that must be followed when reading data from the I²C-bus registers of the TFA9894D detailed in Table 9-3. One byte is transmitted at a time. Each of the registers stores two bytes of data. Data is always written in byte pairs. Data transfer is always MSB first.

The read cycle sequence using SDA is as follows:

1. The microcontroller asserts a start condition (S).
2. The microcontroller transmits the 7-bit device address of the TFA9894D, followed by the R/W bit set to 0.
3. The TFA9894D asserts an acknowledge (A).
4. The microcontroller transmits the 8-bit TFA9894D register address from which the first data byte is read.
5. The TFA9894D asserts an acknowledge.
6. The microcontroller asserts a repeated start (Sr).
7. The microcontroller retransmits the device address followed by the R/W bit set to 1.
8. The TFA9894D asserts an acknowledge.
9. The TFA9894D transmits the first byte (the MSB).
10. The microcontroller asserts an acknowledge.
11. The TFA9894D transmits the second byte (the LSB).

12. The microcontroller asserts either an acknowledge or a negative acknowledge (NA).

- If the microcontroller asserts an acknowledge, the target register address is auto-increased by the TFA9894D and steps 9 to 12 are repeated.
- If the microcontroller asserts a negative acknowledge, the TFA9894D frees the I²C-bus and the microcontroller generates a stop condition (P).

Table 9-3: I²C-bus read cycle

Start	TFA9894 address	R/W	First register address			TFA9894D address	R/W	MSB		LSB		More data...		Stop
S	01101A ₂ A ₁	0	A ADDR	A	Sr	01101A ₂ A ₁	1	A MS1	A	LS1	A	<....>	NA	P

10 Limiting values

$\delta_{i(clk)}$	clock input duty cycle	MCLK	40	-	60	%

- [1] L_{BST} = boost converter inductance; R_L = load resistance; L_L = load inductance (speaker).
- [2] This parameter is not tested during production; the value is guaranteed by design and checked during product validation.
- [3] When C_L exceeds 200 pF, low-power mode must be disabled.
- [4] At power-up, audio is output on OUTP/OUTN after $t_{d(on)amp} + t_{d(on)PLL}$.
- [5] Intended for Speaker protection. In combination with Goodix speaker protection, a speaker temperature accuracy of ± 10 °C can be realized.
- [6] Recommended setting.
- [7] The system is less sensitive to jitter when the PLL is locked on FS.

12.3 TDM timing characteristics

Table 12-3: TDM bus interface characteristics

All parameters are guaranteed for $V_{BAT} = 4.0$ V; $V_{DD} = 1.8$ V; $V_{DDE} = 3.3$ V; $V_{DDP} = V_{BST} = 10$ V, adaptive boost mode; $L_{BST} = 1 \mu$ H^[1]; $R_L = 8 \Omega$ ^[1]; $L_L = 44 \mu$ H^[1]; $f_i = 1$ kHz; $f_s = 48$ kHz; $T_{amb} = 25$ °C; default settings, unless otherwise specified.

Symbol	Parameter	Conditions	Min	Typ	Max	Unit
f_s	sampling frequency	pin FS; audio mode	[2] 16	-	48	kHz
		on pin FS; 96 kHz mode	-	96	-	kHz
f_{clk}	clock frequency	on pin BCK; audio mode	[2] $32f_s$	-	$384f_s$	kHz
		on pin BCK; 96 kHz mode	-	-	$96f_s$	kHz

		DATA edge to BCK HIGH	10	-	-	ns
t_h	hold time	BCK HIGH to FS edge	[3] 10	-	-	ns
		BCK HIGH to DATA edge	10	-	-	ns

- [1] L_{BST} = boost converter inductance; R_L = load resistance; L_L = load inductance.
- [2] The TDM bit clock input (BCK) is used as a clock input for the amplifier and the DC-to-DC converter. The BCK and FS signals must be present for the clock to operate correctly.

[3] This parameter is not tested during production; the value is guaranteed by design and checked during product validation.

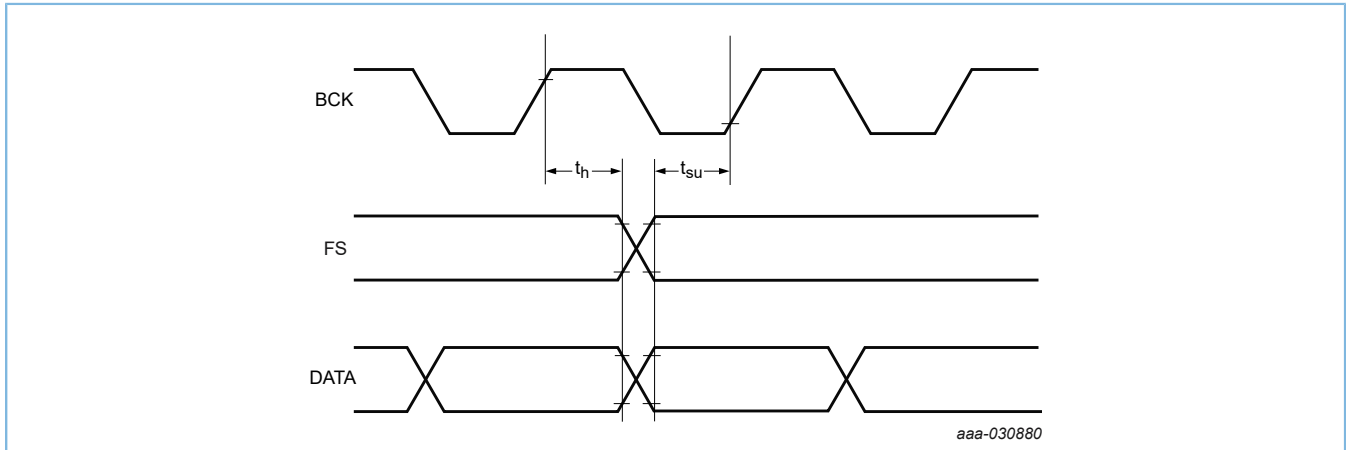

Figure 12-1: TDM timing

12.4 I²C timing characteristics

Table 12-4: I²C-bus interface characteristics

All parameters are guaranteed for $V_{BAT} = 4.0\text{ V}$; $V_{DDD} = 1.8\text{ V}$; $V_{DDE} = 3.3\text{ V}$; $V_{DDP} = V_{BST} = 0\text{ V}$, adaptive boost mode; $L_{BST} = 1\text{ }\mu\text{H}^{[1]}$; $R_L = 8\text{ }\Omega^{[1]}$; $L_L = 44\text{ }\mu\text{H}^{[1]}$; $f_i = 1\text{ kHz}$; $f_s = 48\text{ kHz}$; $T_{amb} = 25\text{ }^\circ\text{C}$; default settings, unless otherwise specified.

Symbol	Parameter	Conditions	Min	Typ	Max	Unit
f_{SCL}	SCL clock frequency		-	-	400	kHz
t_{LOW}	LOW period of the SCL clock		1.3	-	-	μs
t_{HIGH}	HIGH period of the SCL clock		0.6	-	-	μs
t_r	rise time	SDA and SCL signals	^[2] $20 + 0.1 C_b$	-	-	ns
t_f	fall time	SDA and SCL signals	^[2] $20 + 0.1 C_b$	-	-	ns
$t_{HD,STA}$	hold time (repeated) START condition		^[3] 0.6	-	-	μs
$t_{SU,STA}$	set-up time for a repeated START condition		0.6	-	-	μs
$t_{SU,STO}$	set-up time for STOP condition		0.6	-	-	μs
t_{BUF}	bus free time between a STOP and START condition		1.3	-	-	μs
$t_{SU,DAT}$	data set-up time		100	-	-	ns

Symbol	Parameter	Conditions	Min	Typ	Max	Unit
$t_{HD;DAT}$	data hold time		0	-	-	μs
t_{SP}	pulse width of spikes that must be suppressed by the input filter		[4] 0	-	50	ns
C_b	capacitive load for each bus line		-	-	400	pF

- [1] L_{BST} = boost converter inductance; R_L = load resistance; L_L = load inductance (speaker).
- [2] C_b is the total capacitance of one bus line in pF. The maximum capacitive load for each bus line is 400 pF.
- [3] After this period, the first clock pulse is generated.
- [4] To be suppressed by the input filter.

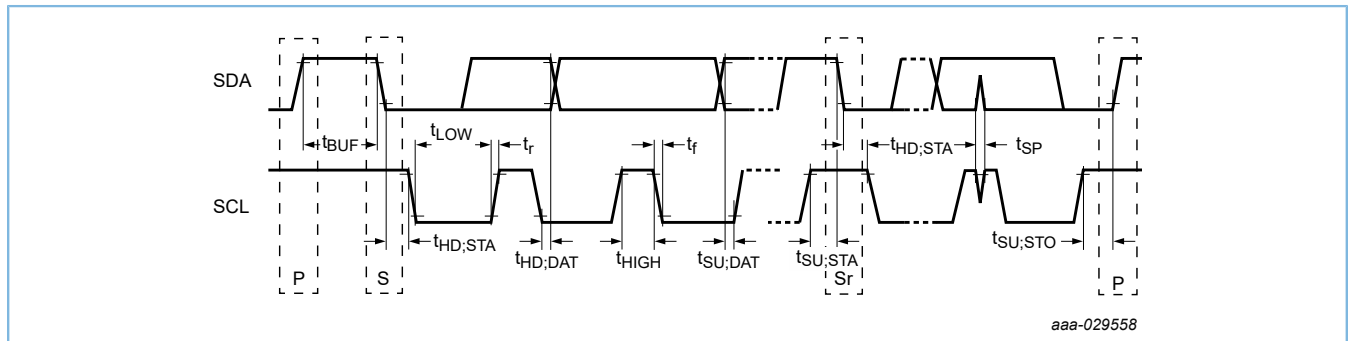

Figure 12-2: I2C timing

13 Application information

13.1 External components

The DC-to-DC converter requires a battery supply voltage capacitor (C_{VBAT}), an output capacitor (C_{VDDP}), and an inductor (L_{BST}) to work properly. The nominal values of these components are 22 μF , 33 μF , and 1 μH , respectively. If a larger coil is used, the capacitance must also be increased. A 1 μF decoupling capacitor (C_{VDDD}) must be connected close to the VDDD pin. A 1 μF decoupling capacitor (C_{VDDE}) must be connected close to the VDDE pin. The VDDD pin must be connected externally to the 1.8 V supply and the VDDE pin must be connected externally to the 3.3 V supply. One 4.7 k Ω resistor (R_{VS}) must be connected between each voltage sensing input and its corresponding amplifier output ($VSP/OUTP$ and $VSN/OUTN$).

13.1.1 DC-to-DC converter output capacitor

A ceramic capacitor is required at the output of the DC-to-DC converter (C_{VDDP}).

Capacitors constructed using X5R (-55 °C to +85 °C) or X7R (-55 °C to +125 °C) dielectric materials are preferred because they are compact, feature low ESR, and are sufficiently stable over a wide temperature range. The capacitance value decreases over the DC biasing voltage range (50 % to 85 % decrease). Consequently, the selected capacitor must have a nominal value three to four times higher than the required minimum effective capacitance.

Note: The DC-to-DC converter capacitor connected to pin VBST (C_{VDDP}) is critical for stability. The recommended effective value (the capacitance value at the maximum boost voltage) of C_{VDDP} depends on the coil inductance, and is given in [Table 13-1](#). The position of the capacitor and the layout of the board are also critical. It is recommended to connect C_{VDDP} as close as possible to the BST and GNDB pins without vias in the PCB tracks.

In many applications, it is desirable to limit the height of components as much as possible. This can be achieved for C_{VDDP} by placing two smaller capacitors in parallel. The rated voltage should be 10 V or higher.

Table 13-1: DC-to-DC minimum output capacitor

Effective coil value (at maximum current)		Minimum effective capacitance (at the boost voltage)
0.47 μH		3.4 μF
1 μH	[1]	4 μF
1.5 μH		12 μF
2.2 μH		20 μF

[1] Recommended value; larger values are not preferred because of the cost of and space needed for the coil (L_{BST}) and the capacitor (C_{VDDP}).

The values in the [Table 13-2](#) and [Table 13-3](#) are guaranteed for capacitors rated X5R or higher.

Table 13-2: DC-to-DC recommended output capacitor

Specification	Conditions	Min	Typ	Max	Unit
nominal capacitance; 20 % tolerance	6 Ω or 8 Ω speaker; 1 μH inductor (L_{BST})	-	33	-	μF
minimum effective capacitance	6 Ω or 8 Ω speaker; 1 μH inductor (L_{BST})	4	-	-	μF

Specification	Conditions	Min	Typ	Max	Unit
rated voltage		10	-	-	V

13.1.2 Battery capacitor

C_{VBAT} must be at least half the value of C_{VDDP} .

Table 13-3: Battery recommended capacitor

Specification	Min	Typ	Max	Unit
nominal capacitance; 20 % tolerance	-	22	-	μF
rated voltage	10	-	-	V

13.1.3 DC-to-DC converter inductor

An inductor is required at the output of the DC-to-DC converter (L_{BST}). For stability, the inductance of the coil should remain above $0.33 \mu\text{H}$ and below $2.2 \mu\text{H}$ under all conditions. The most commonly available values are $1 \mu\text{H}$ and $1.5 \mu\text{H}$. A nominal value $1 \mu\text{H}$ provides the optimum balance between current capability, component size, and efficiency.

The choice of inductor is configured using DCCV bit. It is strongly influenced by the impedance of the speaker used in the application. The speaker impedance determines the output current of the DC-to-DC converter. The coil current contains a ripple around the average current resulting in a peak inductor current, $I_{L(\text{peak})}$. The value of the peak inductor current is determined by the minimum required battery voltage, the boost voltage, and the inductor value. Recommended specifications for the DC-to-DC converter inductor are given in [Table 13-4](#).

Table 13-4: DC-to_DC recommended inductor

Specification		Min	Typ	Max	Unit
nominal inductance; 20 % tolerance	[1]	0.47	-	2.2	μH
DC resistance		-	-	100	$\text{m}\Omega$
saturation current		-	4.2	-	A

[1] $0.33 \mu\text{H}$ (min) at $I_{L(\text{peak})}$.

13.2 PCB layout considerations

Great care should be taken when designing the PCB layout for a class-D amplifier and booster circuit since the layout can affect the audio performance, the booster performance, the electromagnetic compatibility (EMC) performance and/or the thermal performance.

13.2.1 DC-to-DC converter stability

To avoid stability problems, the DC-to-DC converter output capacitor must be connected as close as possible to GNDB/GNDP via thick tracks as well as to V_{BST}/V_{DDP} in the top layer.

13.2.2 EMC considerations

EMC standards define to what degree a (sub)system is susceptible to externally imposed electromagnetic influences and to what degree a (sub)system is responsible for emitting electromagnetic signals in standby and in normal operating modes.

EMC immunity and emission values are normally measured over a frequency range from 180 kHz up to 3 GHz.

The coupling capacitors on pins V_{DD} , V_{DDP} , and V_{BAT} and the booster inductor L_{BST} should be placed close to the TFA9894D, referenced to a solid ground plane. The design should include a solid ground plane below the IC.

Long speaker cables (or traces) should be avoided when designing a filterless class-D amplifier. Long speaker cables have a negative effect on electromagnetic emissions. Speaker traces/cables of less than 10 cm are recommended.

13.2.3 Power supply considerations

Since V_{DDE} and V_{DDD} are supplied on difference sources (3.3 V for V_{DDE} and 1.8 V for V_{DDD}), it must be ensured at platform level that the ramping up of the V_{DDE} is achieved prior to the V_{DDD} and the ramping down of the V_{DDE} is achieved after the V_{DDD} . When V_{DDE} is absent, the IO must not be driven externally.

15 Soldering of WLCSP packages

15.1 Introduction to soldering WLCSP packages

This text provides a very brief insight into a complex technology. More information about handling, packing, shipping and soldering of moisture/reflow sensitive surface-mount devices can be found in IPC/JEDEC J-STD-033 and IPC/JEDEC J-STD-020.

Wave soldering is not suitable for this package.

All Goodix WLCSP packages are lead-free.

15.2 Board mounting

Board mounting of a WLCSP requires several steps:

1. Solder paste printing on the PCB
2. Component placement with a pick and place machine
3. The reflow soldering itself

15.3 Reflow soldering

Key characteristics in reflow soldering are:

- Lead-free versus SnPb soldering; note that a lead-free reflow process usually leads to higher minimum peak temperatures (see [Figure 15-1](#)) than a SnPb process, thus reducing the process window.
- Solder paste printing issues, such as smearing, release, and adjusting the process window for a mix of large and small components on one board.
- Reflow temperature profile; this profile includes preheat, reflow (in which the board is heated to the peak temperature), and cooling down. It is imperative that the peak temperature is high enough for the solder to make reliable solder joints (a solder paste characteristic) while being low enough that the packages and/or boards are not damaged. The peak temperature of the package depends on package thickness and volume and is classified in accordance with [Table 15-1](#).

Table 15-1: Lead-free process (from J-STD-020D)

Package thickness (mm)	Package reflow temperature (°C)		
	Volume (mm ³)		
	< 350	350 to 2 000	> 2 000
< 1.6	260	260	260
1.6 to 2.5	260	250	245
> 2.5	250	245	245

Moisture sensitivity precautions, as indicated on the packing, must always be respected.

Studies have shown that small packages reach higher temperatures during reflow soldering (see [Figure 15-1](#)).

Figure 15-1: Temperature profiles

For further information on temperature profiles, refer to IPC/JEDEC J-STD-033 and IPC/JEDEC J-STD-020.

15.3.1 Stand off

The stand off between the substrate and the chip is determined by:

- The amount of printed solder on the substrate
- The size of the solder land on the substrate
- The bump height on the chip

The higher the stand off, the better the stresses are released due to thermal expansion coefficient (TEC) differences between substrate and chip.

15.3.2 Quality of solder joint

A flip-chip joint is considered to be a good joint when the entire solder land has been wetted by the solder from the bump. The surface of the joint should be smooth and the shape symmetrical. The soldered joints on a chip should be uniform. Voids in the bumps after reflow can occur during the reflow process in bumps with high ratio of bump diameter to bump height, i.e. low bumps with large diameter. No failures have been found to be related to these voids. Solder joint inspection after reflow can be done with X-ray to monitor defects such as bridging, open circuits and voids.

15.3.3 Rework

In general, rework is not recommended. By rework, we mean the process of removing the chip from the substrate and replacing it with a new chip. If a chip is removed from the substrate, most solder balls of the chip are damaged. In that case it is recommended not to reuse the chip again.

Device removal can be done when the substrate is heated until it is certain that all solder joints are molten. The chip can then be carefully removed from the substrate without damaging the tracks and solder lands on the substrate. Removing the device must be done using plastic tweezers, because metal tweezers can damage the silicon. The surface of the substrate should be carefully cleaned and all solder and flux residues and/or underfill removed. When a new chip is placed on the substrate, use the flux process instead of solder on the solder lands. Apply flux on the bumps at the chip side as well as on the solder pads on the substrate. Place and align the new chip while viewing with a microscope. To reflow the solder, use the solder profile shown in IPC/JEDEC J-STD-033 and IPC/JEDEC J-STD-020.

15.3.4 Cleaning

Cleaning can be done after reflow soldering.
